Sparse Coding for Image Classification
- Vector quantization
- Sparse coding
- Locality-constrained Linear Coding
- Experiment results & Application
Background

• (Hubel, Weisel, 1962-68) The human visual system, at the primary cortex (V1), has receptive fields that are:
  • spatially localized
  • oriented
  • bandpass
• Let $x$ in $\mathbb{R}^m$ be a signal.

• Let $D = [d_1, \ldots, d_p] \in \mathbb{R}^{m \times p}$ be a set of normalized “basis vectors”

• $D$ is “adapted” to $x$ if it can represent it with a few basis vectors—that is, there exists a sparse vector in $\mathbb{R}^p$ such that $x \approx D$. We call the sparse code.
Introduction to Sparse Coding

• Applications

  – Image processing

  – Image classification
Sparse Coding in Image Processing

• Sparse Coding could be used in image processing.
• Two examples will be shown.
Denoising
Since 1699, when French explorers landed at the great bend of the Mississippi River and celebrated the first Mardi Gras in North America, New Orleans has brewed a fascinating melange of cultures. It was French, then Spanish, then French again, then sold to the United States. Through all these years, and even into the 1900s, others arrived from everywhere: Acadians (Cajuns), Africans, indige-
Sparse Coding in Image Classification

- **Input:** feature vectors of interest points in a 2D image
- **Local sparse coding**
- **Multi-scale max pooling**

Images shown: Puma, Flamingo, Hedgehog, Butterfly, Pizza, Saxophone.
Introduction to Image Classification

- Tasks: assigning the input image with one of the predefined classes.
Image Classification is difficult!

- Problems: view point changes, lighting changes, high intra-class variations, background noise.
Image Classification Framework

- Feature Extraction
- Building Dictionary
- Coding
- Pooling
- Classification
Feature Extraction

- Local Descriptors-SIFT

  - Compute image gradients at each location
  - Histogram of the gradient orientation (8 bins)
  - Concatenate histograms of 4 x 4 spatial grid
  - Feature Dimension:
    8 orientation x (4x4) spatial grid = 128
Feature Extraction

- We often use dense sift to capture global image information, as follow:
Bag-of-feature Model

- SIFT + Bag of Word representation.
- Treat image as a collection of local “visual words”
- Vector quantize the “visual words” to get a histogram representation

However, can not capture the spatial information of these local “visual words”.
Spatial Pyramid Matching

• SPM(spatial pyramid matching)
• Pooling histograms from different spatial locations across multiple spatial scales
Building Dictionary

1. Image
2. Feature Extraction
3. Descriptor
4. Coding
5. Pooling
6. SPM
7. Concatenating
8. Feature vector [ ]
Building Dictionary

• K-means; Sparse Coding; Structured Dictionary

• Example:

  Natural Images

\[
\begin{align*}
\text{Dictionary with bases } (\phi_1, \ldots, \phi_{64})
\end{align*}
\]

\[
\begin{align*}
&\approx 0.8 \times \begin{bmatrix}
0, & \ldots, & 0, & 0.8, & 0, & \ldots, & 0, & 0.3, & 0, & \ldots, & 0, & 0.5, & \ldots
\end{bmatrix} \\
&\quad + 0.3 \times \begin{bmatrix}
0, & \ldots, & 0, & 0.8, & 0, & \ldots, & 0, & 0.3, & 0, & \ldots, & 0, & 0.5, & \ldots
\end{bmatrix} \\
&\quad + 0.5 \times \begin{bmatrix}
0, & \ldots, & 0, & 0.8, & 0, & \ldots, & 0, & 0.3, & 0, & \ldots, & 0, & 0.5, & \ldots
\end{bmatrix}
\end{align*}
\]
Coding

- Representing descriptors by dictionary bases.
- Hard Quantization (VQ)
- Soft Quantization (SC, LLC)

\[
\begin{bmatrix}
0 \\
0 \\
1
\end{bmatrix}
\]

\[
\begin{bmatrix}
0.3 \\
0.1 \\
0.6
\end{bmatrix}
\]

\[\approx 0.3\phi_1 + 0.1\phi_2 + 0.6\phi_3\]
Pooling

Combining feature detectors into a ‘global feature’ that preserves task-related information while removing irrelevant details.

average pooling:

\[ f_a(k) = \frac{1}{N} \sum_{i=1}^{N} z_i(k), \ k = 1, 2, ..., K. \]

max pooling:

\[ f_m(k) = \max_{i} |z_i(k)|, \ k = 1, 2, ..., K. \]
Average Pooling vs. Max Pooling

Clutter is homogeneous across images.

When the clutter has high variance, distributions remain well separated with max pooling, but have significant overlap with average pooling.
Classification

• Usually SVM with linear or non-linear kernels (intersection, chi-square, etc.)

• One vs all strategy for multiclass
Sparse Coding for Image Classification

- Feature descriptor obtained from dense SIFT and BoF representation.
- To improve image classification accuracy, well-designed coding method is needed.
Vector Quantization
Vector Quantization

Let $X$ be a set of SIFT appearance descriptors in a $D$-dimensional feature space, i.e. $X = [x_1, \ldots, x_M]^T \in \mathbb{R}^M \times D$. The vector quantization (VQ) method applies the K-means clustering algorithm to solve the following problem:

$$\min_V \sum_{m=1}^M \min_{k=1\ldots K} \|x_m - v_k\|^2$$

where $V = [v_1,\ldots,v_K]^T$ are the $K$ cluster centers to be found, called codebook, and $\| \cdot \|$ denotes the L2-norm of vectors.
Vector Quantization

- The optimization problem can be re-formulated into a matrix factorization problem with cluster member-ship indicators $U = [u_1,...,u_M]^T$.

$$\min_{U,V} \sum_{m=1}^{M} \|x_m - u_m V\|^2$$

subject to $Card(u_m) = 1, |u_m| = 1, u_m \geq 0, \forall m$

- In training phase: the optimization is solved with respect to both $U$ and $V$.
- In coding phrase: $V$ will be applied for a new set of $X$. 

Vector Quantization

• **Drawbacks of VQ:**
  – Large quantization error
  – Non-linearly separable (SVM with nonlinear kernel).

• **Drawbacks of nonlinear SVM:**
  – nonlinear kernels, e.g. the intersection kernel or the chi-square kernel.
  – computational complexity: $O(n^3)$
  – memory complexity: $O(n^2)$ in the training phase (n is the training size)
Sparse Coding

- Input Image
  - SIFT Extraction
  - Vector Quantization
  - Spatial Pooling

- Feature Extraction
  - (a) Nonlinear SPM
  - (b) Linear ScSPM

- Classification
  - Nonlinear Classifier
  - Linear Classifier
Sparse Coding

- Sparse Coding is an extension of VQ.

\[
\begin{align*}
\min_{U,V} \quad & \sum_{m=1}^{M} \|x_m - u_m v\|^2 + \lambda |u_m| \\
\text{subject to} \quad & \|v_k\| \leq 1, \quad \forall k = 1, 2, \ldots, K \\
\min_{U,V} \quad & \sum_{m=1}^{M} \|x_m - u_m v\|^2 \\
\text{subject to} \quad & \text{Card}(u_m) = 1, |u_m| = 1, u_m \geq 0, \forall m
\end{align*}
\]

- constraint Card(um) = 1 may be too restrictive
- Not putting a L1-norm regularization on \(U_m\), which enforces \(U_m\) to have a small number of nonzero elements.
Sparse Coding

• A unit L2-norm constraint on $V_k$ is applied to avoid trivial solutions.
• Similar to VQ, SC has a training phase and a coding phase.
• Training phase: solving the equation with respect to U (code) and V (dictionary) alternatively.
• Coding phase: for each descriptor X, the SC codes are obtained by optimizing with respect to U only.
SC Versus VQ

• SC coding can achieve a much lower reconstruction error
• SC more specialize and could capture salient properties of images
• Image patches are sparse signals.
• Reduces the complexity of SVMs to $O(n)$ in training and a constant in testing.
Improving Sparse Coding

Intuitions:

• Sparse coding is slow.
• A descriptor may be represented by very dissimilar bases.
• Similar descriptors may be represented by very different bases and codes.
Adding local constraint

- Locality is more essential than sparsity (K.Yu et al. 2009).
- Locality must lead to sparsity but not vice versa.

\[
\min_{U, V} \sum_{m=1}^{M} \|x_m - u_m V\|^2 + \lambda |u_m| \\
\text{subject to } \|v_k\| \leq 1, \quad \forall k = 1, 2, \ldots, K
\]

\[
\min_U \sum_{m=1}^{M} \|x_m - u_m V\|^2 + \lambda |d \odot u_m|^2 \\
\text{subject to } 1^T U = 1
\]

- Where \( \odot \) denotes the element-wise multiplication, and \( \text{dist}() \) is the Euclidean distance.

\[
d = \exp\left(\frac{\text{dist}(x_m, V)}{\sigma}\right)
\]
Properties of LLC

- Better reconstruction than VQ
- Local smooth sparsity
- Faster than SC (from $O(MK)$ to $O(M+K^2)$, where $K<<M$)
Approximated LLC for fast encoding

• Use K-NN of x as the local bases Bi

\[
\min_{\tilde{C}} \sum_{i=1}^{N} \| x_i - \tilde{c}_i B_i \|^2
\]

\[
st. \ 1^T \tilde{c}_i = 1, \ \forall i.
\]

• Computational Complexity: O(M + K^2)
Applications

- Scene Classification
- Object Recognition
- Action Recognition
- Face Recognition
- Hand Written Digit Recognition
Scene Classification

15 Scenes

The dataset contains 4485 images falling into 15 categories: office, living room, kitchen, bedroom, store, tall building, street, industrial, inside city, highway, coast, open country, mountain, forest, suburb. Each category contains 200 to 400 images, and we randomly take 100 of them as training for this category.

Object Recognition

Caltech101
The Caltech-101 dataset contains 102 classes (including animals, vehicles, faces, flowers, etc.) with high shape variability. The number of images per category varies from 31 to 800. Most images are medium resolution, i.e., about $300 \times 300$ pixels.

- **KSPM**: nonlinear SPM with histograms.
- **KC**: nonlinear SPM with soft assignment for histograms.
- **LLC**: linear SVM.
Action Recognition

TRECVID Surveillance Event Detection Evaluation

- 100 hours of surveillance videos, 10 hours each day, from London Gatwick International Airport.
- 50 hours of annotated videos for training, and the rest 50 hours of videos for testing.
- We evaluated on 3 event detection tasks: cellphone to ear, object put, and pointing.
- Very large scale, only linear classifiers applicable.

Face Recognition

CMU PIE Database

The dataset contains 41368 images of 68 people, each person with under 13 poses, 43 different illumination conditions with 4 different expressions. We use five near frontal poses (C05, C07, C09, C27, C29) for our evaluation.
